ABSTRACT

Introduction: Liver fibrosis is one of the most common clinical manifestations of hepatic diseases. However, though many synthetic drugs exist for the treatment and prevention of liver diseases, liver injuries still persist. The present study, therefore, sought to investigate the subacute protective effects of *Acalphya wilkesiana* against carbon tetrachloride (CCl_4)-induced toxicity in animals. **Methodology**: Liver injury was induced in experimental animals by administering CCl_4 (1:1 v/v in olive oil, intraperitoneally (i.p.), twice weekly for 8 weeks) after pre-treatment with extract of *A. wilkesiana* (AWE). AWE (250 mg/kg) and Silymarin (120 mg/kg) were administered orally (daily for 8 weeks). The hepatoprotective effect was studied by assaying the activity of liver enzymes, such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), and alpha-fetoprotein. The effect of the treatments on liver prooxidants (*e.g.* malondialdehyde [MDA]) and antioxidants (*e.g.* superoxide dismutase [SOD], reduced glutathione [GSH], glutathione peroxidase [GPx], and glutathione transferase [GST]), as well as inflammatory cytokines (e.g. interleukin [IL]-17, IL-23, nuclear factor kappa beta [NF-kB], and cycloxygenase-1 [COX-1]) and the histology of the liver were also examined. **Results**: The activity of liver function biomarkers changed significantly upon CCl_4 administration; increases in ALT, total and direct bilirubin, and some fibrosis indices (*e.g.* alpha-fetoprotein and APRI [p<0.05-0.001, compared with normal]) were observed. Co-administration of AWE with CCl_4 restored these to normal levels. The intensity of structural alterations revealed that the AWE treatment has protective potential against subacute liver injury. AWE treatment also reduced the expression of IL-17, 1L-23, NF-kB and COX-1, underscoring its anti-inflammatory properties. **Conclusion**: The results of the current study generally suggest that hydroethanolic leaf extracts of *A. wilkesiana* inferno possess some subacute protective activity by improving liver function and inhibition of inflammation, and could be developed as a potent antifibrotic agent.

Key words: Acalypha wilkesiana inferno, carbon tetrachloride, hepatoprotective effect, medicinal plants, interleukins

INTRODUCTION

The liver serves as the main hub for important activities such as metabolism, secretion, detoxification and storage. When any of these functions is distorted, liver damage is said to have occurred[1]. Although many synthetic drugs exist for the treatment and prevention of ailments, even for liver diseases, liver injuries still persist[2]. According to the WHO, nearly 2.4 million deaths are associated with liver injury and damage annually[1].

Liver fibrosis is one of the most common clinical manifestations of hepatic diseases. It is the excessive amassing of the extracellular protein matrix, including collagen, elastin, fibronectin, laminin and proteoglycans in the liver[3]. These proteins are generated from activated hepatic stellate cells (HSCs). Activation of HSCs is associated with increased mRNA expression of collagen, tumor growth factor-β (TGF-β), and alpha-smooth muscle actin (α-SMA)[4]. Liver fibrosis is caused by chronic hepatic injury and is associated with inflammation-associated conditions, such as alcoholic and non-alcoholic steatohepatitis, viral hepatitis, and even autoimmune diseases[3]. Several anti-fibrotic therapies, therefore, target either the activated HSCs or are anti-inflammatory in action[3]. Meanwhile, cirrhosis is the end stage of several liver diseases and is an irreversible form of liver fibrosis. Together with liver fibrosis, cirrhosis is responsible for several mortalities and morbidities worldwide, especially in developing countries[4].

Hepatotoxins are agents that cause liver damage. There are several examples of hepatotoxins, and these are grouped into intrinsic and idiosyncratic hepatotoxins. Some common hepatotoxins include ethanol, carbon tetrachloride, and acetaminophen, among others. Agents that protect the liver from deleterious effects of hepatotoxins are said to be hepatoprotective[1]. Carbon tetrachloride (CCl_4) is a well-known intrinsic hepatotoxin, first reported as a cause of liver injury in 1936[5]. It is widely used for the study of liver inflammation, fibrosis and cirrhosis. It belongs to a group of hepatotoxins which needs to be metabolized by the mixed-function oxidases in the liver. Once metabolized by cytochrome P450 oxidases, CCl_4 generates trichloromethyl radical ($CCl_3O\cdot$), a very reactive free radical which results in primary and secondary bond formation (a covalent bond formation with DNA, proteins, lipids and carbohydrates, and generation of free radicals, lipid peroxidation, *etc.*, respectively)[6]. Thus, $CCl_3O\cdot$ is responsible for the several toxic effects following carbon tetrachloride administration.

The numerous side effects of synthetic drugs spur the growing interest of medical researchers in the evaluation of traditional herbal formulations[2]. These formulations are relatively safer[7]. Medicinal plants also have the advantages of being cheaper and more readily available.

Acalypha wilkesiana Mull Arg 'Inferno' (family Euphorbiaceae) is an ornamental plant grown as a hedge. It is commonly called the copperleaf and is widely distributed in the tropics. Few pharmacological and phytochemical assessments have been done on the species. According to Larbie *et al.*[8], the hydroethanolic extract of the plant contains triterpenoids, alkaloids, flavonoids, glycosides, coumarins, sterols, and hydrolysable tannins. The study also revealed high antioxidant and significant bactericidal activities of *A. wilkesiana*. The species has also been demonstrated to improve the clearance of glucose and is toxicologically safe in animals[9,10]. A recent study also demonstrated the nephroprotective activity of the plant in gentamicin- and cisplatin-induced nephrotoxicity[11], while the 250 mg/kg dose was demonstrated to possess the highest acute hepatoprotective activity[12]. Furthermore, the protective effect of aqueous leaf extracts of *A. wilkesiana* 'Godseffiana', a related cultivar, has been reported[13]. The present study, thus, sought to investigate the subacute hepatoprotective effects of *A. wilkesiana* against CCl_4-induced toxicity in animals based on biochemical and histological assessment, non-invasive anti-fibrotic evaluation, and inflammation.

MATERIALS - METHODS

Drugs and chemicals

Formalin, ethylene diamine tetraacetic acid (EDTA), and sodium dihydrogen phosphate were obtained from Sigma (St. Louis, MO), and Silymarin (Legalon 70, Bukwang Param, Seoul, Korea). Assay kits for biochemical parameters were obtained from ELITECH (Paris, France). All reagents and solvents were of analytical grade.

Animals

The animals used in the study, Sprague-Dawley rats (14-week old males, 170-230 g in weight), were obtained from the University of Ghana Medical School, Korle-Bu, Ghana and maintained in the animal holding facility of the Department of Biochemistry and Biotechnology, KNUST, Kumasi. They were kept in metal cages comfortably bedded with wood shavings and at a constant temperature of 22-25 ^oC, with 12 h light and 12 h dark cycle. The animals had free access to standard feed (Mash, AGRICARE, Kumasi-Ghana) and tap water *ad libitum* except in an overnight fast before the first treatment and sacrifice. In the experimental grouping of the animals, their body weights were taken into consideration to achieve approximately equal conditions among the groups. The animals were given color codes on their tails using permanent markers for easy identification. All animals were humanely handled during the experiment and conducted following the guidelines of the Committee for the Purpose of Control and Supervision of Experiment on Animals (CPCSEA, New Delhi, India) and the National Research Council's Guide for Care and Use of Laboratory Animals[14]. The study protocol was reviewed and approved by a veterinarian on the research team.

Plant preparation and extraction

A. wilkesiana leaves were collected and prepared as previously described[8–10]. Briefly, the leaves were identified as *A. wilkesiana* inferno, previously described as *A. inferno* (voucher number KNUST/HM/2017/L018), air-dried under shade, and milled. The 50% hydroethanolic extract was prepared (100 g in 1000 ml, repeated twice), concentrated (at 45^oC under pressure using Buchi R205, Switzerland), freeze-dried (Labconco, England), and designated as the hydroethanolic extract of *A. wilkesiana* (AWE, yield of 11.5%).

Experimental design

Subacute liver injury was achieved in animals by a slightly modified method of Tipoe *et al.*[15]. The animals were sorted into four groups (n = 5): Group 1, the control group was given the vehicle (1 ml distilled water and 1 ml/kg b.wt. olive oil on respective days of CCl$_4$ administration); Group 2 was given 1 ml/kg of CCl$_4$ (1: 1 v/v in olive oil, ip); Group 3 was administered with CCl$_4$ + Silymarin (120 mg/kg in normal saline by oral route); and Group 4 was administered with CCl$_4$ + AWE (250 mg/kg in normal saline by the oral route which was previously determined to be a safe dose with hepatoprotective activity)[9,15]. The CCl$_4$ alone was administered twice a week (every Wednesday and Friday) for 8 weeks. Silymarin and AWE were administered once daily throughout the entire duration of the experiment. Rats were anesthetized and sacrificed at the end of the 8 weeks after an overnight fast.

Effect of treatment on hematology and biochemical parameters

At termination, animals were fasted overnight and exposed to light ether anesthetization. Incisions were then made at the cervical regions using a sterile blade and blood collected into EDTA tubes for hematology analyses using the Sysmex Hematology System (USA). The following parameters were assayed: hemoglobin concentration (HGB), red blood cell (RBC) count, red cell indices [mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), and red cell distribution width (RDW)], platelet count, white blood cells (WBC), lymphocytes, hematocrit, plateletcrit, platelet distribution width (PDW), and platelet large cell ratio (P-LCR).

Part of the blood was collected into gel-activated tubes, allowed to clot, and centrifuged at 3500 rpm for 10 minutes. The serum obtained was analyzed for liver function parameters [*i.e.* alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), and bilirubin (total, direct and indirect)], lipids [total cholesterol (TChol), triglycerides (Trig), very low-density lipoproteins (VLDL), and high-density lipoproteins (HDL)], and alpha-fetoprotein using the Selectra E (Vital Scientific, Japan) and reagents from ELITECH (France).

The animals were dissected, and the livers were removed, cleared of fat, washed with normal buffered saline and blotted to dry. They were weighed to obtain the absolute liver weight (ALW). The relative liver weight (RLW) was calculated as a function of the body weight at sacrifice.

Histology and liver antioxidant assays

A tissue section of the liver (right lobe) was stored in 10% buffered formalin and processed for histological assessment using standard methods. The specimens were stained with hematoxylin and eosin. Photomicrographs were taken and analyzed by a pathologist. Part of the liver was stored in phosphate-buffered saline (PBS) and 5 g was homogenized separately in 10 ml of 100 mM KH$_2$PO$_4$ buffer containing 1 mM EDTA (pH 7.4), and centrifuged at 12,000 rpm for 30 min at 4°C. The supernatant was collected and used for liver pro- and anti-oxidant parameters, including total protein, superoxide dismutase (SOD)[16], malondialdehyde (MDA)[17], reduced glutathione (GSH)[18], glutathione peroxidase (GPx)[19], and glutathione transferase (GST)[20].

Immunohistochemical analysis

The immunohistochemical staining was performed using the Streptavidin-biotin peroxidase complex kit (M IHC Select Detection System, HRP/DAB, Merck, Germany LOT: 2775482) with a slight modification of the procedure, as previously described by Jarikre and Emikpe[21] and previously used[22]. Rabbit monoclonal to NF-kB (2A12A7), COX-1 (19999, Lot # L1113), IL-17 (SAB3701439, Lot R127357), and IL-23 (Cat. # 06-1079, Lot # 2914943) were used as primary antibodies. Goat Anti-Rabbit IgG (HRP, ab6721) was used as the secondary antibody. Tissue sections from the control rats served as negative controls. The photomicrographs were taken with the aid of a digital camera (Amscope MU900) attached to the microscope. The images were quantified for staining intensity using the reciprocal intensity of the stained markers on the open-source Fiji (ImageJ) software. The optical density of the staining intensities was calculated using the formula:

$$OD = \log 10 \frac{Maximum\ Reciprocal\ Intensity}{Mean\ Reciprocal\ Intensity}$$

Data analysis

Results were analyzed with GraphPad Prism 7 (GraphPad Software Inc., La Jolla, CA, USA). The results (body weights, hematological parameters, serum biochemistry, and antioxidants) were recorded as mean $\pm$ standard error of mean (SEM). Data were subjected to one-way ANOVA and Tukey's multiple comparison test at a significance value of 5%. Indices of fibrosis including AST/ALT, aspartate aminotransferase to platelet ratio index (APRI), and AST/PLT ratios were calculated.

RESULTS

Effect of treatment on liver weight

Figure 1 shows the effect of treatment on the absolute and relative liver weights. CCl_4 and AWE treatment resulted in significant increases in absolute but not relative liver weight.

Effect of treatment on some hematological parameters

Table 1 shows the effect of treament on some hematological parameters of animals. Treatment had no significant effect on the haematological parameters, except for a decrease in platelet (PLT) levels in CCl_4-only treated group ($p < 0.05$). AWE and Silymarin treatment restored PLT levels to near normal.

Effect of treatment on serum biochemical parameters and liver oxidative stress status

Table 2 shows the effect of treatment on the biochemical and antioxidant profiles of animals. CCl_4 treatment resulted in significant increases in ALT, AST, ALP and bilirubin levels. Silymarin and AWE treatment resulted in decreases in these functions to near-normal levels. No significant changes were observed for the pro- and anti-oxidant status of the liver, except for an increase in the levels of reduced GSH in Silymarin co-treated group.

Effect of treatment on some indices of liver fibrosis

Table 3 shows the effect of the treatment on some non-invasive indices of liver fibrosis. CCl_4 resulted in significant increases in AFP and AST/PLT ratio and decreases in AST/ALT ratio and APRI. Silymarin and AWE prevented fibrosis based on observations with AFP. APRI was significantly lower in the Silymarin group compared with CCl_4-only group, while the AST/PLT ratio was reduced in the AWE group.

Effect of Treatment on Liver Histology

Figure 2(**A-D**) shows representative liver sections of normal and treated groups. CCl_4 treatment resulted in severe hepatocellular vacuolar degenerations with extensive coagulation necrosis of hepatocytes, inflammation, and fibroblast proliferation (**Figure 2B**). Silymarin and AWE treatment reversed these injuries to near normal architecture, especially as it relates to the necrosis of hepatocytes, as there were a few regenerative hepatocytes.

Effect of treatment on expression of pro-inflammatory cytokines

Figure 3 shows the micrograph of liver sections of normal and treated groups for the expression of interleukin (IL)-17 and 23, nuclear factor kappa-light-chain-enhancer of activated B cells (NF-kB) and cyclooxygenase-1 (COX-1). **Figure 4** shows the percent intensity of the expression of the cytokines. CCl_4 treatment resulted in the overexpression of these cytokines while AWE treatment suppressed these to near-normal levels.

DISCUSSION

Liver damage is associated with a significant increase in the serum levels of some enzymes which are normally segregated in the parenchymal cells of the liver. Examples of these enzymes include AST, ALP and ALT[3]. CCl_4 administration increased the serum levels of the aforementioned enzymes, indicative of liver damage. CCl_4, an intrinsic liver toxin, is known to mediate its toxic activity by the generation of free radicals and induction of oxidative stress[5]. Once metabolized, CCl_4 results in primary and secondary bond formation (a covalent bond formation with DNA, proteins, lipids, and carbohydrates), which results in cell damage. Damage to the hepatocytes then leads to the leakage of these enzymes into the serum[6]. Previous studies revealed the presence of flavonoids and hydrolysable tannins in the hydroethanolic extracts of *A. wilkesiana*, and these possess high antioxidant activity[8]. This explains the observed decrease in the ALT, AST and ALP levels upon administration of CCl_4 and AWE. In the case of AST and ALP, the levels were near normal.

Consistent with results from a previous study, administration of 1 ml/kg b.wt. CCl_4 intraperitoneally for 8 weeks resulted in a marked increase in the serum bilirubin levels (direct and indirect) and a decrease in total cholesterol and triglyceride levels[23]. This is indicative of liver damage. However, administration of plant extract did not have any significant effect on the serum cholesterol and triglyceride levels.

There is a common association between hepatic fibrosis and oxidative stress. Free radicals result in peroxidation of membrane lipids, thereby leading to cell damage. Thus, antioxidants may help in reducing the progression of liver fibrosis[24]. Results from this study showed no significant effects of CCl_4 on MDA levels; however, there was some decrease in the GSH levels. Decreased GSH levels upon CCl_4 administration was also observed in the previous studies[25]. High antioxidant activity evident by high concentrations of

flavonoids and tannins in the hydroethanolic extract of *A. wilkesiana*[8] explains the increase in GSH levels in the CCl_4+AWE group. The increase was, however, very prominent in the Silymarin-treated group, confirming the high degree of hepatoprotection.

Biopsy of the liver remains the ultimate technique for assessing hepatopathies[26], such as for example, detecting and determining the stage of fibrosis in non-alcoholic steatohepatitis[27]. The procedure is invasive, however, and has risks of serious complications. Other cost-effective and useful means that are easy to measure and handle include platelet count, AST/ALT ratio, AST-to-platelet ratio index (or APRI), *etc.*[26] An increase in the APRI was seen in the CCl_4 control group. Administration of Silymarin and AWE resulted in a decrease in the APRI. Blood platelet levels and AST levels are known to decrease and increase respectively with fibrosis progression[26]. Thus, an increase in APRI is shown to be an index of the severity of hepatic disease[28], even in animal models. Though the APRI alone is likely not sufficiently sensitive to rule out significant disease, the lower the
Figure 2: **Micrographs of liver sections of normal and treated rats**. (**A**) Normal group showing no observable lesion. (**B**) CCl$_4$ only showing bridging hepatocellular vacuolar degeneration (blue arrow), spotty necrosis (red arrow) within flammation (black arrow) and fibroblasts response (white arrow). (**C**) CCl$_4$ + Sily showing moderate centrilobular hepatocellular vacuolar degeneration (blue arrows) and regenerative hepatocytes (green arrows). (**D**) CCl$_4$ + 250 mg/kg AWE showing moderate centrilobular vesicular hepatocellular degeneration (blue arrows), regenerative hepatocytes (green arrows) and Kupffer cell hyperplasia (black arrow) (HE stain, X400; scale bar = 20 μm)

APRI score (less than 0.5), the greater the negative predictive value (and ability to rule out cirrhosis); the higher the value (greater than 1.5), the greater the positive predictive value (and ability to rule in cirrhosis)[29]. CCl$_4$ was, therefore, confirmed to have caused hepatotoxicity, which was reversed in the AWE and Silymarin-treated groups.

The current study showed that Silymarin and AWE improved PLT levels compared with CCl$_4$-only group. Cirrhotic rats induced with dimethylnitrosamine and 70% hepatectomy were demonstrated to have improved platelet levels by a single intravenous injection of thrombopoietin which correlated with the inhibition of HSC activation and decrease of the fibrotic area in the liver, while antiplatelet serum attenuated hepatic regeneration[30]. It has been suggested that platelets may promote hepatocyte proliferation by secreting hepatocyte growth factor (HGF), a potent mitogen for hepatocytes. HGF is known to activate MET receptor essential for organogenesis and wound healing. Further, HGF may contribute to the resolution of fibrosis by modulating levels of TGF-β and matrix metalloproteinases (MMPs), which are the main ECM enzymes degrading collagen[31]. Platelets are known to induce hepatic regeneration by directly interacting with hepatocytes by promoting cell cycle progression and metabolic pathways in hepatocytes[32].

Furthermore, as mentioned earlier, AWE and Silymarin treatments restored the histology of the liver after CCl$_4$ damage to near normal architecture. Also, the high expression of IL-17, IL-23, NF-κB and COX-2 in the CCl$_4$ treated group shows the necrotic and inflammatory reactions in CCl$_4$-induced toxicity. NF-κB and COX-1 as pro-inflammatory signals and their roles in liver fibrosis have been well established[33,34]. IL-17 has been shown to directly promote the production of IL-6 and IL-8 in human dermal fibroblasts[35] with *in vitro* studies showing an increased proliferation of fibroblasts in vascular endothelial cells, suggesting the pivotal role of IL-17 in fibrosis and endothelial inflammation[36,37]. IL-17 is
Figure 3: **Effect of treatment on the expression of IL-17, IL-23, NF-κB and COX-1 in liver cells**. Streptavidin-biotin complex Horseradish immunoperoxidase with Haematoxylin counterstain (x 400; scale bar = 20 μm)

Figure 4: **Effect of treatment on percent expression of IL-17, IL-23, NF-κB and COX-1**. CCl$_4$ treatment included over-expression of pro-inflammatory cytokines while Silymarin and AWE down-regulated these to near-normal levels. Each bar is a mean of 5 animals. Statistical difference: ^{a}: different from Normal at p < 0.05 –0.001; ^{b}: different from CCl$_4$ only at p < 0.05 – 0.001; ^{c}: different from CCl$_4$ + Sily at p < 0.05 – 0.001.

a major pro-inflammatory cytokine involved in neutrophil recruitment[38]. IL-23 is a pro-inflammatory heterodimeric cytokine composed of an IL12B (IL-12p40) subunit (that is shared with IL12) and the IL23A (IL-23p19) subunit[39]. In psoriasis, IL-23 expression is markedly upregulated, compared to normal skin[40], and also in chronic bowel inflammation[41]. Thus both IL-17 and 23 are significantly involved in inflammation, leading to fibrosis. In the current study, AWE was observed to significantly downregulate the expression of these pro-inflammatory molecules, underscoring the healing properties of the extract.

It can be suggested that the subchronic protective effect of *A. wilkesiana* 'inferno' leaf extracts on the liver of animals against CCl_4-induced toxicty is by protecting tissues membranes from peroxidation, leakage of enzymes, and improvement of the microstructure. Also, the extracts protect against the overexpression of pro-inflammatory cytokines and related activities leading to cell death.

CONCLUSION

This study indicates that *Acalypha wilkesiana* 'inferno' possesses subacute protection against CCl_4-induced toxicity by reducing the levels of ALT, ALP and AST, as well as AFP, AST/PLT ratio and APRI. The protective effect of this extract was supported by histological and immunohistochemistry observations. Thus, 50% hydroethanolic extract of *A. wilkesiana* inferno can be developed as an effective hepatoprotective agent which brings about the functional improvement of liver function and can be exploited as a therapeutic agent against liver fibrosis.

ABBREVIATIONS

α-**SMA**: alpha-smooth muscle actin
AFP: alpha-fetoprotein
ALP: alkaline phosphatase
ALT: alanine aminotransferase
ALW: absolute liver weight
APRI: aspartate aminotransferase to platelet ratio index
AST: aspartate aminotransferase
AWE: *Acalypha wilkesiana* hydroethanolic extract
CCl$_4$: Carbon tetrachloride
COX-1: clyclooxygenase-1
DBil: direct bilirubin
DNA: deoxyribonucleic acid
GPx: glutathione peroxidase
GSH: reduced glutathione
GST: glutathione transferase
HCT: haematocrit

HDL: high density lipoproteins
HGB: haemoglobin concentration
HSC: hepatic stellate cells
IBil: indirect bilirubin
IL-17: interleukin-17
IL-23: interleukin-23
LYM: lymphocytes
MCH: mean corpuscular haemoglobin
MCHC: mean corpuscular haemoglobin concentration
MCV: mean corpuscular volume
MDA: malondialdehyde
mRNA: messenger ribonucleic
Nfkβ: nuclear factor kappa B
PCT: Plateletcrit
PDW: platelet distribution width
P-LCR: platelet larger cell ratio
PLT: platelet
RBC: red blood cell
RDW: red cell distribution width
RLW: relative liver weight
SOD: superoxide dismutase
TBil: total bilirubin
TChol: total cholesterol
TGF-β: tumour growth factor-β
Trig: triglycerides
VLDL: very low density lipoproteins
WBC: white blood cell
WHO: world health organization

ACKNOWLEDGMENTS

AUTHOR'S CONTRIBUTIONS

C. Larbie conceived and designed the experiments; analyzed and interpreted the biochemical and hematological data; BO Emikpe and T.A. Jarikre contributed reagents and performed all histology and immunohistochemical experiments; A.A. Oyagbemi contributed reagents and performed all liver antioxidant experiments; C. Larbie, C. Owusu Adjei, R.A. Nyarko and E.B. Aseidu managed all literature search and drafted the manuscript. All authors approved the final manuscript.
